Oregon State University

CLAMS

Landscape Planning and Analysis Process

CLAMS

Forest policies influencing land management

Ownership	Policy	Goals	Strategies
Forest Service / Bureau of Land Management	Northwest Forest Plan; Individual Forest Plans	Late-successional / old-growth forest conditions; T&E species; aquatic systems; commodity production	Reserves; Matrix; Green tree retention; Adaptive management areas
State	State Forest Plans	Healthy forests; Commodity production; T&E species	Structure-based management; Habitat Conservation Plan
Industry / Non-Industrial Private	Organizational Policies; State Forest Practices Act	Commodity production; Protect environment and fish / wildlife habitat	Retain trees in clearcuts; Streamside protection rules

CLAMS

Spatial units recognized

BSUs

Parcels

Harvest Blocks

Land Allocations

4th Field Watersheds

5th Field Watersheds

Land Ownerships

CLAMS

Management intentions (what landowners intend to do)

Need to make assumptions for each landowner group:
Federal, State, Forest Industry, Non-Industrial Private

Key assumptions:

Timing and intensity of
treatments

Minimum clearcut harvest ages

Spatial considerations:

green-up

blocking of management units
for treatment

Regeneration stand management
intensity

How do we arrive at the assumptions?

Landowner surveys conducted by the Oregon Department of
Forestry

Numerous meetings with landowners and land managers

Research

CLAMS

Policy guidance (what landowners have to do)

Need to make assumptions for each landowner group:

Federal, State, Forest Industry, Non-Industrial Private

Key policies:

Riparian management

Leave trees (clumps)

Owl reserves

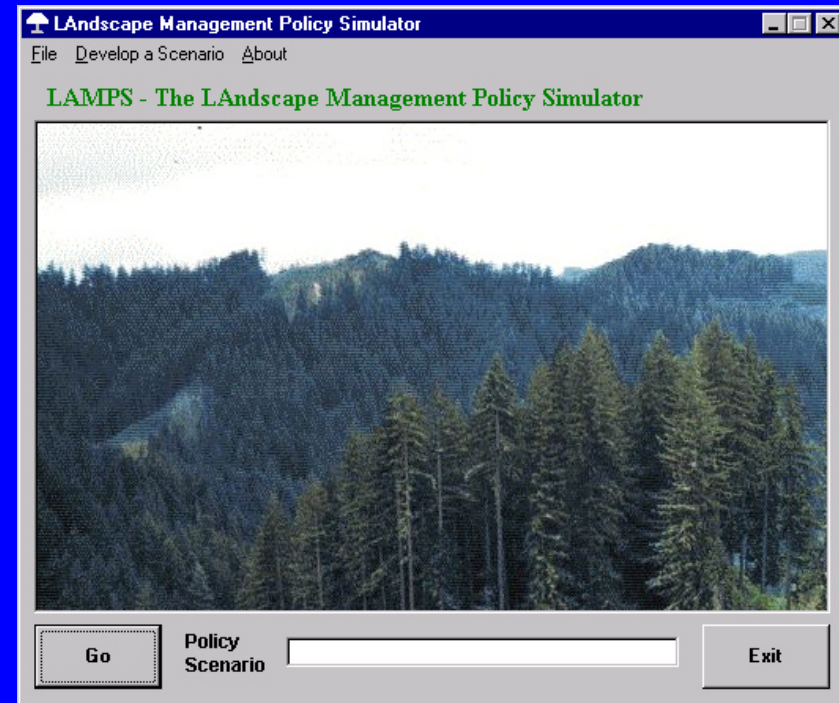

Interior habitat areas

Structure-based management

Simulation Results

LAMPS

What is it ?

- A simulation model that seeks to emulate management behavior of four landowner groups: federal, state, forest industry, non-industrial private.
- A model that allows an evaluation of forest policies across a large area, and over a long time frame.
- A model that merges strategic and tactical planning considerations so that processes at a variety of spatial and temporal scales can be represented, and to facilitate an analysis of biological effects at a scale appropriate for the species / function being considered.
- A Model I formulation of forest management behavior that seeks to represent some “aspiration” of a group of landowners.

LAMPS

Simulation Notes

Projections are for 100 years, with 5-year time steps.
All ownerships must be classified as either federal, state, forest industry, or non-industrial private.
Classification of owners and owner policies is flexible.
Maximum area simulated: Depends on computer's RAM

LAMPS

Software

User Interface: Visual Basic

LAMPS

Management Options

“Federal” scheduling process

Monte Carlo approach to scheduling clearcuts.

Constraints:

A maximum percentage of “matrix” land area can be clearcut in any one 5-year time period.

A minimum amount of “older forest” within a watershed must be present before any clearcuts can be scheduled in that watershed.

Can set a target (upper bound) number of acres to be clearcut or thinned in each time period.

Can set a target (upper bound) amount of volume to be harvested in each time period.

LAMPS

Management Options

“State” scheduling process

Monte Carlo approach to scheduling clearcuts.

Objective is measured by the achievement of maximum even-flow of timber harvest volume, using binary search.

Constraints:

Achievement of structural conditions by State management District.

Maintain a distribution of sizes of Interior Habitat Area (IHA) patches (essentially older forest conditions spatially connected).

LAMPS

Management Options

“Forest Industry” scheduling process

Value maximization approach to scheduling clearcuts.

Objective can be measured by the achievement of maximum even-flow of timber harvest volume, using binary search.

Alternatively, target harvest levels can be set by the user as goals to achieve.

Constraints:

Attempt to emulate a historical clearcut size distribution by “blocking” management units together for harvest using a dynamic process (block patterns are not fixed).

LAMPS

Management Options

“Non-Industrial Private” scheduling process

Harvest probability approach to scheduling clearcuts.

No clear objective function to maximize, although target harvest levels can be set by the user as goals to achieve.

Constraints:

Attempt to emulate a historical clearcut size distribution.

LAMPS

Spatial Considerations

- Adjacency relationships among clearcut harvests
- Clearcut size distributions
- Owl habitat areas
- Interior Habitat Areas
- Federal watershed conditions
- State District forest structure conditions

LAMPS

Riparian Management Choices

- 1) No harvest within Oregon Forest Practices Act buffers.
- 2) Allow partial cutting within Oregon Forest Practices Act buffers, to the extent allowed by the Act.
- 3) Choice #2, yet no harvest of hardwoods within 100 feet of a stream.
- 4) Choice #1, and no harvest of hardwoods within 100 feet of a stream.

1	No harvest in FPA buffers Harvest of other hardwoods within 100 ft	Harvest in FPA buffers Harvest of other hardwoods within 100 ft	2
4	No harvest in FPA buffers No harvest of other hardwoods within 100 ft	Harvest in FPA buffers No harvest of other hardwoods within 100 ft	3

LAMPS

Leave Tree Strategies

- 1) Leave Oregon Forest Practices Act minimums (2 small TPA).
- 2) Leave 2 large TPA.
- 3) Leave 5 TPA, according to State Forest Plan guidelines.
- 4) Leave 14 TPA according to State Forest Plan guidelines.
- 5) Leave clumps of trees (BSUs, as a percentage of land area) uncut.

LAMPS

Transition Probabilities

After clearcutting, each BSU within a clearcut unit has a probability of being regenerated as one of four types: open, hardwood, mixed, or conifer.

Probability = f (previous forest type, owner, ecoregion, distance from stream)

		Distance from stream (m)			
		0-50	51-100	101-150	151+
From hardwood to:					
Open / semi-closed		0.10	0.05	0.05	0.03
Hardwood		0.10	0.10	0.10	0.07
Mixed		0.30	0.25	0.15	0.10
Conifer		0.50	0.60	0.70	0.80
Total		1.00	1.00	1.00	1.00
From mixed to:					
Open / semi-closed		0.05	0.05	0.02	0.02
Hardwood		0.10	0.05	0.03	0.03
Mixed		0.25	0.20	0.15	0.05
Conifer		0.60	0.70	0.80	0.90
Total		1.00	1.00	1.00	1.00
From conifer to:					
Open / semi-closed		0.05	0.02	0.02	0.01
Hardwood		0.05	0.03	0.03	0.01
Mixed		0.15	0.10	0.05	0.03
Conifer		0.75	0.85	0.90	0.95
Total		1.00	1.00	1.00	1.00

LAMPS

Stochastic Events

During the scheduling process, we model small gap disturbances by examining each BSU and determining whether or not to “regenerate” it (and not “harvesting” the volume).

Disturbance = f (BSU size, distance from stream)

The screenshot shows a dialog box titled "Stochastic Gap Disturbances" with a close button (X) in the top right corner. Below the title bar is the subtitle "Probability of Disturbance by BSU Size". The main content is a table with three columns: "BSU size (pixels)", "Riparian probability", and "Upland probability". The table lists 32 rows, numbered 1 to 32. The "Riparian probability" column contains the value 0.0045 for every row. The "Upland probability" column contains the value 0.0045 for every row. The "BSU size (pixels)" column contains the integers 1 through 32. The table is styled with a light gray background and black text.

BSU size (pixels)	Riparian probability	Upland probability
1	0.0045	0.0045
2	0.0045	0.0045
3	0.0045	0.0045
4	0.0045	0.0045
5	0.0045	0.0045

LAMPS

Summary

The LAMPS simulation model is a spatial simulation model of landowner management behavior, and is associated with a quantitative projection of stand structures.

It was designed to help policy makers and land managers “think through” forest policies before implementing them.

It facilitates spatial analysis of biological effects of policies (using wildlife habitat suitability models).
